### ABSTRACT

Archaeological evidence for the earliest human presence in western Iberia is summarised and discussed. Western Iberia is geologically characterised by magmatic and metamorphic rocks (Hesperian Massif) but also by siliciclastic and carbonate Mesozoic and Cenozoic formations. The geological context affects the distribution of Pleistocene archaeological sites, as the most of the archaeological evidence known today is located in river terrace formations or in karst deposits. Very few sites have been fully investigated; the older ones are tentatively dated as middle/late Middle Pleistocene. Recent results have been obtained using an archaeological and geomorphological approach carried out in the Portuguese region of Alto Ribatejo. Dating of the lithic assemblages found in fluvial terraces or in cave deposits indicates that the first human presence in Portugal is not older than the OIS 8–9. However, it remains difficult to explain the long chronological gap between the archaeological evidences in western Iberia and the older sites in central and eastern Iberia, such as those in the Sierra de Atapuerca and Guadix Baja areas.

### 1. Introduction to the earliest archaeological contexts in western Iberia

The Iberian Peninsula presents a significant diversity in the geological structure and, consequently, in geomorphological features. The Hesperian Massif, formed by Palaeozoic and Pre-Cambrian metasediments and igneous rocks, dominates central Iberia, whereas the western and southern borders consist of Mesozoic and Cenozoic sedimentary successions, mainly siliciclastics and limestones (Fig. 1).

The Iberian fluvial network comprises five main rivers: Tejo (Tajo), Douro (Duero), Guadiana, Ebro and Guadalquivir. Only the Ebro drains to the Mediterranean Sea. The Tejo and the Douro rivers have their mouths on the western Atlantic coast, and the Guadiana and Guadalquivir rivers in the southern coast (Fig. 1).

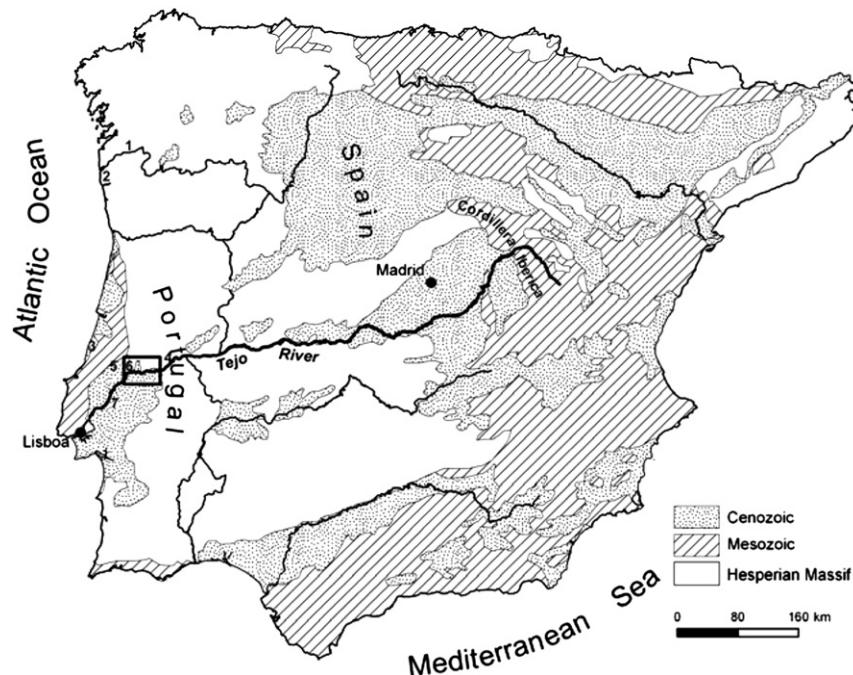

Most of the archaeological evidence known today is located in river terraces or in karst deposits. Studies of the evidence, notably lithic assemblages, have been carried out since the end of the 19th century (Ribeiro, 1871; Cabral, 1881; Serpa Pinto, 1932) and

considerably increased after the 1940s (e.g. Breuil and Zbyszewski, 1942, 1945; Ribeiro, 1943; Zbyszewski, 1943, 1946, 1953, 1958; Breuil, 1959). The typological approach, the influence of Biberson (1961a, 1961b, 1976), on the concept of northern African Pre-Acheulean complexes, and the “Gibraltar Strait hypothesis” as being the “gateway” from Africa to Europe in earlier times (Penalva, 1978), led several authors to suggest a Lower Pleistocene human presence in western Iberia, witnessed by the “Pebble Industries” of the Portuguese littoral (Azevedo et al., 1979; Penalva, 1980; Raposo, 1985; Raposo and Carreira, 1986; Raposo and Santonja, 1996) as well as by some sites in western Spain (e.g. El Aculadero) (Querol and Santonja, 1983).

Although a Lower Pleistocene occupation of the Iberia peninsula is well documented in several contexts, particularly those related with the Sierra de Atapuerca and Guadix-Baza regions (Carbonell et al., 2008), the Western Iberia lithic industries, most located in Portugal and tentatively attributed to a very ancient human presence, are characterised mainly by surface assemblages. These artefacts usually show different patinas, a undefinable mixture of typological features, and have been tentatively dated relative to the age of the geological formation situated below, ages of which are not always well constrained (e.g. Penalva, 1978, 1980; Azevedo et al., 1979; Cardoso and Penalva, 1979; Zbyszewski et al., 1979, 1981, 1982).

**Fig. 1.** Map of the Iberian Peninsula with the archaeological areas and sites mentioned in Table 1: 1 – Portomaior; 2 – Formation M9, Marinho, Vila Praia de Âncora Norte and Formation M10; 3 – Formation F1b, Quinta do Cônego/Pousias, Casal de Santa Maria and Casal do Azemel; 4 – Monte Famaco; 5 – Galeria Pesada; 6 – Ribeira da Atalaia and Fonte da Moita; 7 – Vale do Forno 3/Milharós and Vale do Forno 8.

To date, very few sites have been investigated using an integrated geoarchaeological approach. The most ancient ones have been tentatively dated as middle/late Middle Pleistocene following mainly typological attributions of lithic implements (e.g. Cunha Ribeiro et al., 1989; Cunha-Ribeiro, 1990, 1993, 1996–1997, 2002; Raposo, 1993; Raposo et al., 1993).

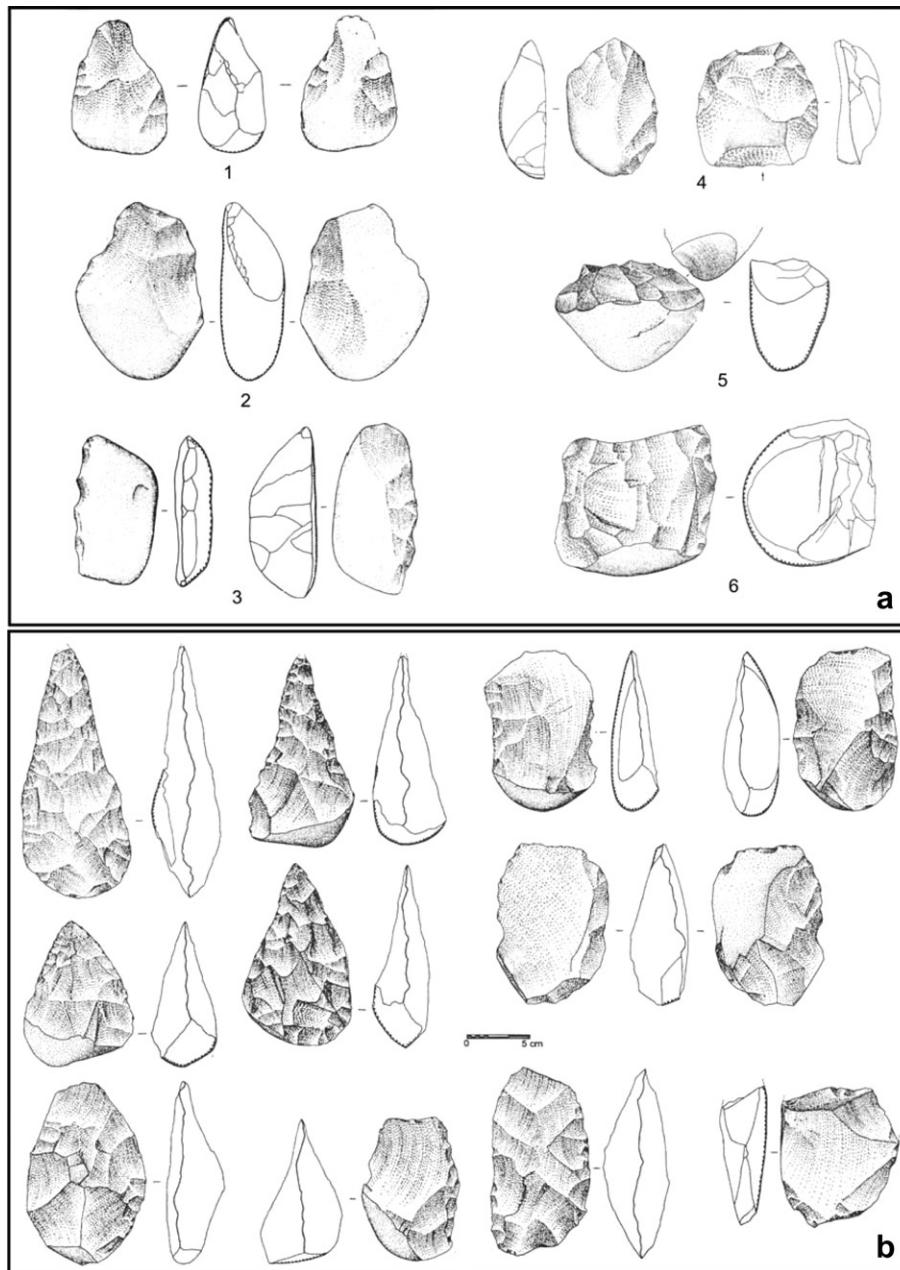

The studies performed at the archaeological sites located in the “middle” terrace of the Tejo River, near the Alpiarça village, are an example of research based on the typology of the lithic implements combined with geomorphologic studies. In the Vale do Forno and Vale da Atela (Fig. 1), within the two main sedimentary units of the middle terrace of the Tejo River, the Lower Gravels and the Upper Sands, several sites have been excavated and subject to detailed studies, including TL dating (Mozzi et al., 2000). Artefacts related with the Lower Gravels unit are scarce and essentially result from surface surveys. The sites associated with the Upper Sands unit, however, are more relevant, namely the sites of Vale do Forno 1, 3 and 8. The VF1 lithic implements consist of a not very evolved Acheulean type (Middle Acheulean). Preliminary typological analysis shows “a high percentage of flaked pebbles, unifacial choppers, and hand axes, commonly of quite rough manufacture, with many fewer implements on flakes” (Mozzi et al., 2000, p. 364). The VF8 excavation revealed an assemblage of around 3000 artefacts which have not been extensively published, but are described as “an Upper Acheulean industry with many tools on flakes and bifaces with good flaking technique” (Mozzi et al., 2000, p. 365). Finally, the lithic assemblage from the VF3, also known as Milharós (Raposo et al., 1985; Raposo et al., 1993; Raposo, 2002), is considered as a Late Acheulean of Micoquian type, this cultural attribution based on the typological features of some lanceolate and micoquian bifaces (Mozzi et al., 2000, p. 365) (Fig. 2).

In summary, following typological criteria, the lithic industries of the sites are considered as representative of a Palaeolithic cultural sequence ranging from Middle Acheulean to Micoquian (Mozzi et al., 2000, p. 365). According to the geomorphologic studies of Mozzi et al. (2000), the cultural sequence matches the

different stratigraphic positions of the sites in the alluvial series. Even if the TL ages are not entirely reliable ( $119 + \infty - 32$  ka correlated with the Micoquian assemblages and  $127 + \infty - 26$  ka for the Middle Acheulean ones) the same authors consider that the dates, “support the archaeological arguments for last interglacial/early phases of the last glacial ages for the VF1, VF8, and VF3 lithic industries and for the U.S. deposits that contain them” (Mozzi et al., 2000, p. 369).

Also in the Tejo valley, but in the region of Vila Velha de Rodão (Fig. 1) detailed geomorphologic studies have been recently published which provide a more precise age for the archaeological materials of the Monte Famaco site, recently considered to represent the T4 terrace of a suite of six terraces identified at the Lower Tejo Basin and dated (IRSL) as  $\geq 280 - 136$  ka (Cunha et al., 2008; Martins et al., 2009). At the Monte do Famaco site (GEPP, 1977; Raposo, 1987, 1993), two series of lithic industries were identified. One comes from the T4 terrace which is made up of a 1-m thick clast-supported gravel-boulder conglomerate, with poor sorting (Cunha et al., 2008). The assemblage is composed of thirty-four worn out quartzite implements tentatively “attributed to the early middle Acheulean (Lower Palaeolithic)” (Raposo, 1987; Cunha et al., 2008, p. 47). The second series of 1500 implements was collected in colluvium at the top of the terrace. Though never extensively published, this assemblage includes, among other lithic morphologies, a high quantity of bifaces and cleavers (Raposo et al., 1993) (Fig. 2).

In the north of Portugal, especially in the littoral between Póvoa de Varzim and Caminha and in the Minho River (Fig. 1), despite the generalised absence of numerical dating, several studies have been done aiming at the establishment of a lithostratigraphic sequence for the Quaternary deposits as well as clarification of its relationship with lithic industries (Texier and Meireles, 1987; Meireles, 1992). These regional studies pointed to the existence of a first human occupation chronologically situated between 250 and 200 ka and related to the MIS 7 (Meireles, 1994, p. 32). The Acheulean cultural attribution of these most ancient assemblages is not

**Fig. 2.** Lithic implements from Monte Famaco site (a): 1–3 – worn out series, 4–6 s serie; and Vale do Forno 3 (b) (after Raposo 1993, 2002).

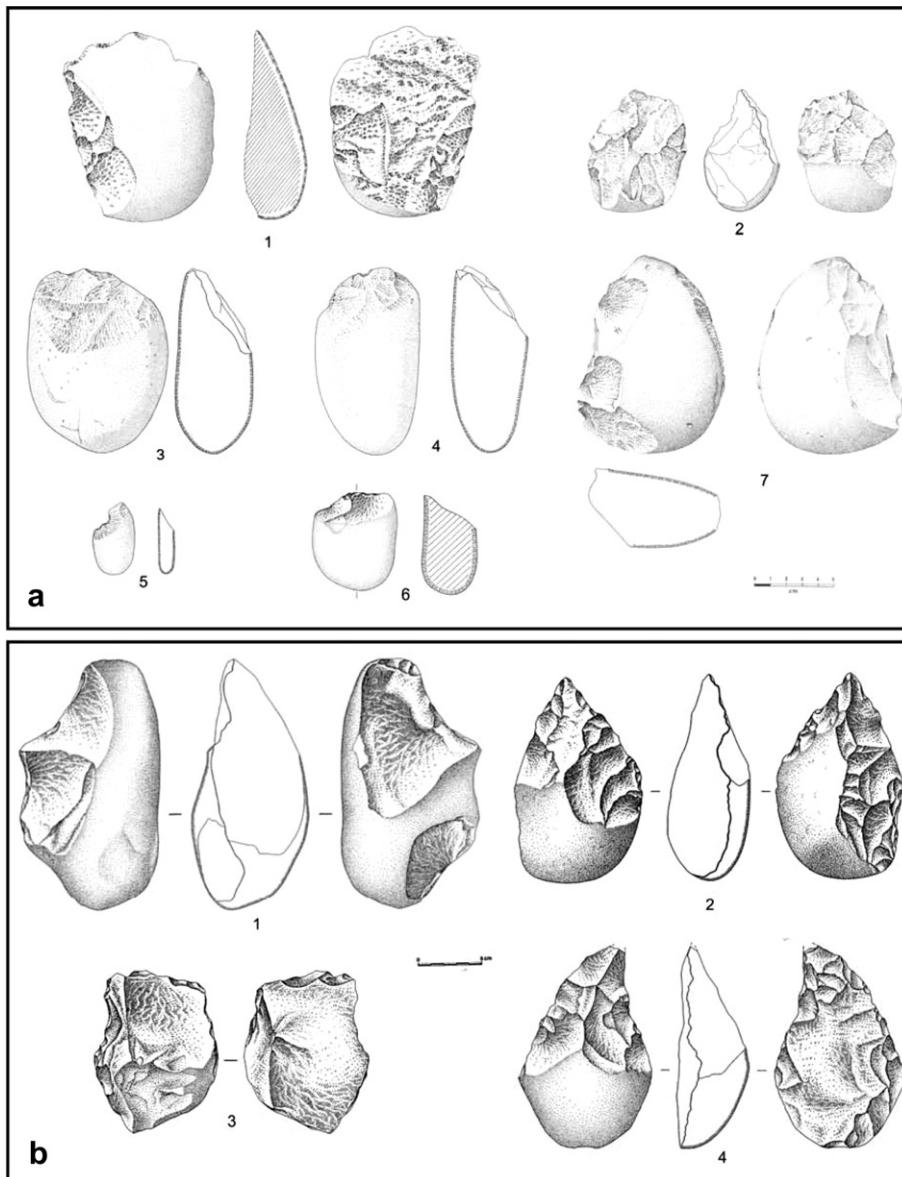

entirely admitted by the author, who underlines the peculiar techno-typological features of the lithic industries in this region, from the late middle Pleistocene into the Holocene, essentially dominated by unifacial tools and unifacial flaking methods, with a substantial presence of worked pebbles (Fig. 3).

The recent discovery of the Portomaior site (Méndez Quintas et al., 2006), adds relevant information to the earliest human occupation of the Minho River due to its clear *in situ* morpho-stratigraphic position. Portomaior is located in the middle terrace (+30 to 40 m) of the Minho River. Four different stratigraphic levels revealed a lithic assemblage considered as Acheulian. Although in the Portuguese northern Atlantic coast bifaces and cleavers are almost absent, here they are well represented (Méndez Quintas et al., 2006, p. 188). Despite of the absence of numerical dating and faunal remains, the relative position of the terrace allows its

attribution to the second half of the Middle Pleistocene. The discovery of the Portomaior site is relevant considering that earlier efforts focused on the problematic stratigraphic sequence of the Gandaras de Bundiño site in the same valley, remain rather inconclusive (Gracia Prieto et al., 2004).

In the coastal zone of central Portugal (Fig. 1) studies done at the Lis River (Cunha-Ribeiro, 1992–1993, 1996, 1999) identified three human occupation stages, associated with Pleistocene fluvial and colluvial deposits, but no numerical dating is available. Nevertheless, the study of the lithic assemblages allowed the characterization of the Acheulean industries' evolution, based on typological criteria, and on their technological features as well: raw material, economy and landscape occupation (Cunha-Ribeiro, 2002).

The available data can be summarised as follows (Cunha-Ribeiro, 2005).

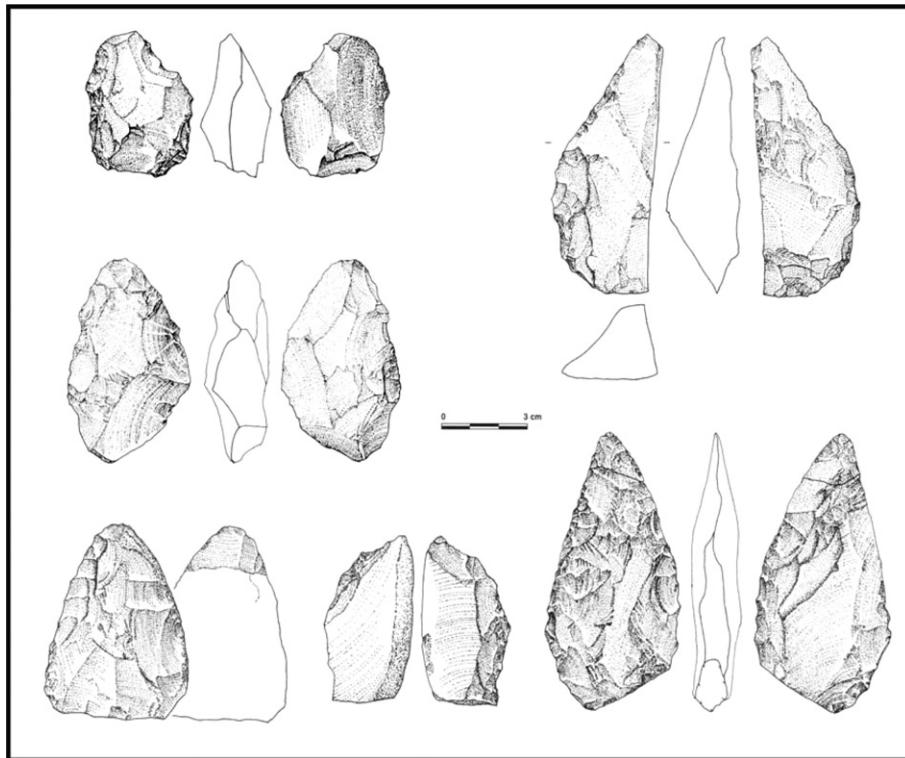

**Fig. 3.** Lithic implements from the Minho region (a): 1 – formation F9, 2 and 7 – Marinho site, 3–6 –Formation M10 (after Meireles, 1992); from the Lis bassin (b): 1 and 2 – Formation F1, 3 – Quinta do Cónego/Pousias, 4 – Casal do Azemel (after Cunha-Ribeiro, 2005).

- The earliest remains are associated with the F1 fluvial formations (Fig. 3) and consist of scattered materials found at the base of sandy deposits. The Pousia/Quinta do Cónego site is also associated with the same formations, but has a higher concentration of artefacts. These are considered to be representative of Acheulian industries. Detailed descriptions are reported in Cunha-Ribeiro (1999).
- A second instance shows a diverse territorial occupation pattern, but the lithic assemblages are quite similar.
- A significant difference appears in the third instance of human occupation, particularly represented in the lithic assemblage of the Casal do Azemel site. Here, although elements such as hand axes and cleavers show a relation with the Acheulean industries, the extensive presence of plano-convex bifacial tools (Fig. 3, n°4) and the centripetal reduction sequence is closer to the Middle Palaeolithic (Cunha-Ribeiro, 1995, 2000).

An exception to the open air/fluvial contexts is the Galeria Pesada Cave (Fig. 1). This cave belongs to the Almonda karst system

and is located in a south-facing cliff, near Torres Novas town in the Portuguese Estremadura region. The excavation of this site started in the early 1990s and the currently published data indicate the existence of a series of geological units within the brecciated deposits (Marks et al., 1999, 2002a, 2002b). These units present five stratigraphic layers that yielded a dense quantity of lithic and bone remains. The abundant faunal assemblage records species that suggest a Middle Pleistocene age for the Galeria Pesada deposits, indicated by the presence of *Corvus cf. antecorax*, which became extinct at the end of the Middle Pleistocene. The numerical dates of a *Equus aff.* and *Mosbachensis* tooth which provided an ESR date of  $241 + 30/-22$  ka corroborate the Middle Pleistocene age. The bone record of this site contains the most ancient human remains so far identified in the Iberian Atlantic coast. Two archaic human teeth, a mandibular canine and a maxillary third molar, have been recovered and considered has being similar to those of other Middle Pleistocene European humans, though no more precise identification on a species level has been accomplished (Trinkaus et al., 2003). The lithic assemblage of Galeria Pesada, essentially

**Fig. 4.** Lithic implements from the Galeria Pesada cave (after Marks et al., 2002a, 2000b).

made on local raw materials (quartzite, quartz, flint and limestone) contains some implements considered as typical Acheulian. The Levallois method is present, but not as extensively as the discoid one, but the authors underline the important component of small asymmetric bifacial tools, partly bifacial tools (points) and bifacial retouched knives, that are, from a morphological point of view, typical of the Micoquian (*Keilmessergruppe*) of central Europe (Marks, 2005) (Fig. 4). Despite the striking morphological resemblance, the author himself states that “while it may be tempting to proclaim possible connection, such seem highly unlikely (...) Within Iberia, there are simply no comparable assemblages of any age. At the moment, the Galeria Pesada assemblages stand alone,

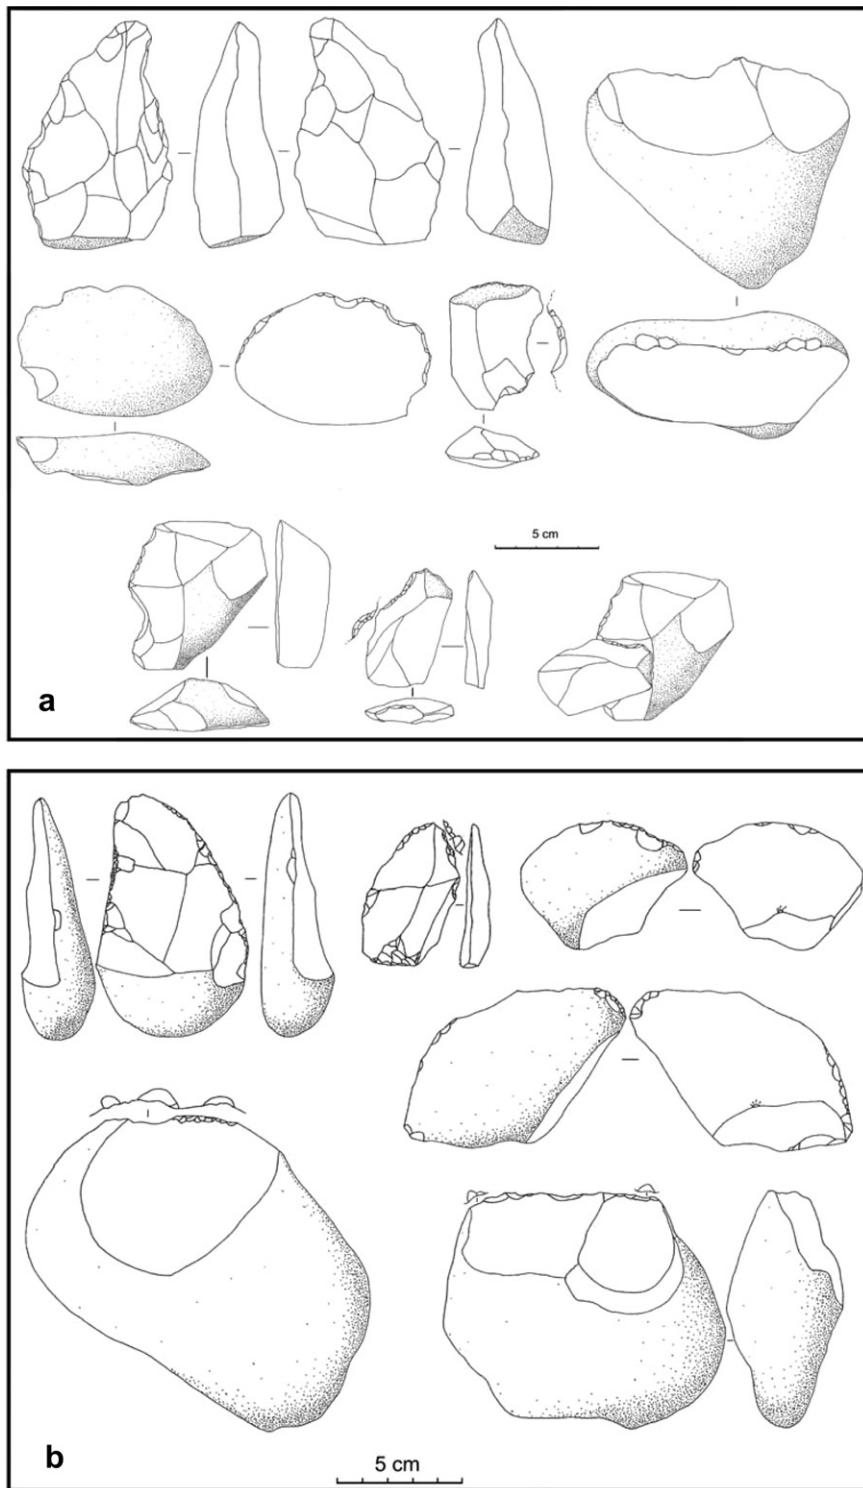

typologically and technologically” (Marks et al., 2002a, 2000b, p. 24). According to the extensive cut marks and other modifications found on faunal bones, extensive butchering and defleshing took place in the site; the assemblages may represent the material remains of, if not base camps, than of camp sites where a range of activities took place.

## 2. New evidence from the Alto Ribatejo (central Portugal)

Apart from the cave deposits, such as Galeria Pesada, the fluvial sequences of the Tejo River offer wide possibilities for dating, as they provide biostratigraphical data that can be compared with

**Table 1**  
Main features of the earliest archaeological contexts of western Iberia.

Area	Site	Geomorphological context	Age	Lithic implements (bifaces + cleavers)
Minho	Portomaior Formation M9	Fluvial terrace	130 (48 + 10)	
	Marinho	Coastal terrace	19 (0 + 2)	
	Vila Praia de Âncora Norte Formation M10	Colluvium	612 (10 + 3)	
		Coastal terrace	160 (0 + 0)	
			140 (0 + 0)	
Lis	Formations F1b	Fluvial terrace	457 (59 + 10)	
	Qta Cónego/Pousias	Fluvial terrace	974 (89 + 42)

numerical ages (e.g. luminescence and U-series dating) and palaeomagnetic studies. However, the chronological framework is a major issue as the range of applications is limited by methodological constraints and spatial coverage is sparse (Santisteban and Schulte, 2007). Knowledge about the evolution of the Tejo fluvial networks has improved during the recent years as more geomorphological, sedimentological, paleontological and geochronological

data has become available, especially in central Iberia (e.g. Pérez-González, 1994; Santonja and Pérez-González, 2000–2001; Gutiérrez-Elorza et al., 2002; Benito et al., 2003; Bridgland et al., 2006; Ortiz et al., 2009).

Similar approaches have been carried out, and are still ongoing, in western Iberia and especially in the Alto Ribatejo region (central Portugal). Here, a developed geoarchaeological perspective shed

more light into the issue of the earliest human presence in this region (Mozzi et al., 1999; Corral, 1998a, 1998b; Rosina, 2002, 2004; Rosina et al., 2005).

In the Portuguese Tejo River, the aggradational terraces consist mainly of coarse-grained siliciclastic gravels and sands, which are generally unsuitable for the preservation of organic remains due to hydrodynamic and diagenetic processes. Nevertheless, a few dates have been obtained for the T6, T5, and T4 lower terraces (Daveau, 1993; Silva et al., 1997; Raposo and Cardoso, 1998; Martins, 1999; Raposo, 2000; Silva, 2003; Cunha et al., 2005, 2008; Martins et al., 2009, in press-a, in press-b) where the most ancient *in situ* lithic implements have been found so far.

**Table 1** summarizes the main features of the earliest archaeological contexts of western Iberia. With the exception of the controversial date for Alpiarça VF8 site, the only dates available are those for the Ribeira Ponte da Pedra open air site (Martins et al., 2009, in press-b; Dias et al., 2010). Both sites are located in the Tejo middle terrace (T4 terrace in the Portuguese Tejo) that is, according with data coming from central Iberia, chronologically related to a final stage of Middle Pleistocene. Most ancient dates are those from the cave site of Galeria Pesada and from the Monte Famaco site (T4 terrace). All these dates seem to suggest that the most ancient human presence in Central Portugal (and consequently, in western Iberia) should be no older than the MIS 8–9.

Very few studies from a behavioural perspective have been carried out so far (see for an example Grimaldi et al., 1998, 1999a, 1999b). The first results seem only to scratch the surface of a wider scenario related to the first human presence in this region.

As far as lithic implements are concerned, technological and functional analyses have been carried out only for the Ribeira Ponte da Pedra and Fonte da Moita lithic assemblages (Grimaldi et al., 2000; Grimaldi and Rosina, 2001; Lemorini et al., 2001; Cura and Grimaldi, 2009; Cristiani et al., 2010). Other lithic assemblages have been analysed by several scholars mainly by typological observations, with special attention to the presence/absence of “typical” Middle Pleistocene morphologies, notably bifaces (in the sense given to these morphologies by the traditional Acheulean or Micoquian definition) (Oosterbeek et al., in press). Bifaces seem to be absent only at Ribeira Ponte da Pedra and Fonte da Moita sites, while they are present in other Ribatejo and Alto Ribatejo sites even if their frequency percentages remain low or very low.

Raw materials do not show relevant variability among sites. Assemblages are made from local quartzite pebbles and boulders, easily collectable everywhere; quartz is also present to a minor extent. Silica is very rare, or absent as in Ribeira Ponte da Pedra and Fonte da Moita, but it is more common in Galeria Pesada, where it is locally collectable.

The Alto Ribatejo lithic assemblages share the main technical and morphological characteristics. The overall feature is an archaic aspect defined by three major groups: (a) worked pebbles; (b) non retouched blanks; (c) retouched blanks. These groups can be viewed as the result of a single and technological simple reduction sequence: pebbles have been knapped in order to produce flakes (mainly cortical or half-cortical ones). The reduced number of flake scars can be associated to an “expedient” production of large/massive blanks and may also indicate a functional need based over quantity, rather than quality of the blanks. More, some of these worked pebbles present features that indicate their utilization as chopping tools (Cristiani et al., 2010).

Formal retouched tools are very rare. Most abundant are blanks characterised by a marginal, coarse retouch not resulting on “classic types” of tools (Fig. 5). These blanks are pebbles (worked or not worked ones) and flakes, mainly on cortical or half-cortical ones. The experimental and functional studies suggest that most of the edges showing this kind of retouch can be attributed to different

types of edge-modifications resulting from subsistence activities, mainly corresponding to the use on hard and very hard materials, mainly scraping, probably wood and horn. Dry hide was scraped, and there is also evidence of meat and bone cutting and scraping, representing butchering activities (Lemorini et al., 2001; Cristiani et al., 2010).

### 3. Conclusions

This brief summary of the archaeological evidence for the earliest human presence in western Iberia aims to introduce the results recently obtained from the integration of geomorphological, sedimentological and archaeological approaches, but also numerical dating, carried out by the authors in the Portuguese region of Alto Ribatejo (see Table 1). The first human presence in the region seems to be no older than MIS 8–9, corresponding to lithic assemblages found at the Tejo River T4 middle terrace or in cave deposits. According to the traditional typological framework, the presence of bifacial tools – even if rare or, in some sites, absent – relate these lithic assemblages to a middle and/or final Acheulean stage according to morphological differences that several scholars consider as chronological markers. The only sites with no bifacial tools, i.e. Ribeira Ponte da Pedra and Fonte da Moita, are characterised by a very “easy-to-produce” technique (which is observed also in the other sites of the region) finalised by the realisation of worked pebbles – in the sense of Choppers and Chopping tools – in order to produce large, cortical flakes. Both pebbles and flakes have been used for multi functional purposes, suggesting a generalised exploitation model of the local natural resources. The lithic assemblages of both Galeria Pesada and VF8 in Alpiarça seem to be an exception to this model thanks to the presence of bifacial implements. Unfortunately, little attention has been paid to the so-called “accompanying” artefacts, i.e. flakes, cores and debris, of these sites. It could be very useful to compare from a technofunctional standpoint the blank categories coming from these sites in order to better evaluate similarities or differences between the “accompanying” industries of sites with bifacial tools and those of sites without bifacial tools.

Although the reported available data are similar to the results obtained from sites in central Iberia, it remains very difficult to explain the chronological gap between this late Middle Pleistocene evidence and the older sites in the Sierra de Atapuerca and Guadix Baja areas. The lack of palaeoenvironmental data and the paucity of faunal data make it difficult for a detailed reconstruction of the landscape. It could be argued that the large presence of the earliest lithic evidences at the base of the Tejo River middle terrace (T4, in a suite of six terraces) is associated with a rapid increase of the human presence in this region, maybe linked with favourable environmental conditions during the MIS 7–9 interval. New archaeological finds, namely in the karst area and in terrace deposits, and numerical dating of the older terraces may provide a better understanding of the human occupation model of western Iberia.
