24 **Running title:** Solubility and stability of stilbene antioxidants

25

26 **Abstract**

27 Aiming at the development of an active food packaging, the goal of this study was to increase
28 stilbenes (resveratrol (RV), pterostilbene (PT) and pinosylvin (PS)) aqueous solubility and
29 stability using hydropropyl-cyclodextrins (HP-CDs) and bile salts. To evaluate stilbene
30 concentration, an HPLC-DAD method was validated. Stilbene solubility was improved by the
31 formation of inclusion complexes and micellar systems with higher solubility values obtained
32 for the inclusion complexes with cyclodextrins. Inclusion complexes revealed a 1:1
33 stoichiometry for RV and PT and a 1:2 for PS. Solid state characterization was carried out using
34 X-ray diffraction, Fourier transform infrared spectroscopy and differential scanning calorimetry.
35 ¹H NMR studies were also performed to characterize the prepared complexes. Photostability
36 studies revealed that CDs were able to increase stilbene photostability at 4 °C. This work showed
37 that stable stilbene solutions can be achieved using hydroxypropyl-CDs, contributing for their
38 incorporation in several materials for the food and pharmaceutical industries.

40 **Keywords:** stilbenes; cyclodextrins; bile salts; HPLC-DAD; photostability; inclusion

41 complexes; micelles

42

43 **Introduction**

44 Stilbenes comprise a class of plant polyphenols that have gained intense interest for their
45 intricate structures and diverse biological activities (Shen, Wang & Lou, 2009). These
46 compounds and their derivatives are of noticeable interest for areas as health and food
47 biotechnology, drug research and development and medicine due to their potential in therapeutic
48 or preventive applications (Shen et al., 2009). Stilbenes exist as both monomers and increasingly
49 complex oligomers. The monomeric stilbene structure is relatively simple and characterized by
50 two benzene rings joined by an ethylene bridge (Kasiotis, Pratsinis, Kletsas & Haroutounian,
51 2013). As a result of this ethylene bridge, stilbenes can occur as *cis*- and *trans*-isomers, of which
52 the *trans*-isomer (E) is the most common configuration (Riviere, Pawlus & Merillon, 2012). So
53 far, different pathways leading to *trans-cis* isomerization have been described such as double
54 bond breakage by radicals, direct photoisomerization under solar or UV irradiation (Riviere et
55 al., 2012) and thermal isomerization (Dugave & Demange, 2003). It is thought that *trans*-isomers
56 are biologically more active than *cis*-isomers. However, the later are not so widely studied and
57 only a few reports comparing the biological activity between the two isomers are available
58 (Anisimova, Kiselevsky, Sosnov, Sadovnikov, Stankov & Gakh, 2011; Campos-Toimil, Elies,
59 Alvarez, Verde & Orallo, 2007; Rius et al., 2010).

60 Stilbenes are widely considered phytoalexins in several plant families for their role in plant
61 resistance to fungal pathogens. For instance, in some plants, stilbenes are constitutively
62 expressed and, furthermore, their synthesis can also be induced in response to a large range of
63 biotic and abiotic stress factors (Riviere et al., 2012). Resveratrol (3,5,4'-trihydroxystilbene,
64 C₁₄H₁₂O₃) pterostilbene (3,5-dimethoxy-4'-hydroxystilbene, C₁₆H₁₆O₃) and pinosylvin (3,5-
65 dihydroxystilbene, C₁₄H₁₂O₂) are known naturally occurring stilbene phytoalexins present in the

66 wood pulp and bark of several trees, in *Vitis vinifera* leaves and berries, in peanuts, mulberries
67 and several plant extracts, such as tea oils and herbal remedies (Bertacche, Lorenzi, Nava, Pini &
68 Sinco, 2006; Lopez-Nicolas, Rodriguez-Bonilla & Garcia-Carmona, 2009a; Lopez-Nicolas,
69 Rodriguez-Bonilla, Mendez-Cazorla & Garcia-Carmona, 2009b).

70 Over the past years, there has been an increased awareness and consumption of foods and
71 supplements containing these stilbenes due to their perceived health benefits. For instance,
72 resveratrol, a vastly studied stilbene, has been associated with several biological activities such
73 as anti-oxidant, anti-inflammatory, analgesic, cardio-protective, neuro-protective, chemo-
74 preventive, anti-aging and antimicrobial activities (Das, Lin, Ho & Ng, 2008; Paulo, Ferreira,
75 Gallardo, Queiroz & Domingues, 2010). Pterostilbene and pinosylvin share many of resveratrol
76 biological activities, including anti-cancer, anti-aging, and antimicrobial activities (Lee et al.,
77 2005; Lin, Yue & Ho, 2009; Macickova et al., 2010; Park et al., 2012). Despite all these
78 established biological activities, the poor solubility of these compounds and their sensitivity to
79 external agents such as air, light, and oxidative enzymes can constitute a serious problem for
80 their bioavailability and, therefore prevent stilbenes from achieving their desirable activity.

81 Several research studies have described that the complexation of polyphenols with cyclodextrins
82 (CDs) and micellar systems led to a marked increase in their aqueous solubility and, even
83 improved their stability and bioactivity (Dai, Chen & Zhou, 2008; Lu, Cheng, Hu, Zhang & Zou,
84 2009).

85 Bile acids are bi-planar natural compounds with two functionally different molecular surfaces: a
86 hydrophobic convex surface of steroid core and a hydrophilic concave surface (Simonovic &
87 Momirovic, 1997). This coexistence of polar and non-polar surfaces in molecules (amphiphilic
88 molecules) induces their self-association in micelles, above a certain bile acid concentration
89 (critical micellar concentration (CMC)), and influences their physical–chemical properties

90 (Atanackovic, Posa, Heinle, Gojkovic-Bukarica & Cvejic, 2009). Micellar solutions of bile acids
91 can solubilise poorly soluble organic substances, improving their resorption and enhancing cell
92 permeability to substances (Atanackovic et al., 2009). Till now, various polymers and oligomers
93 based on bile acids have been prepared for their potential biological and pharmaceutical
94 applications as drug carrier systems, due to its ability to solubilise hydrophobic drugs, as
95 molecular containers, non-polymeric hydrogelators and chemosensors (Atanackovic et al., 2009).
96 CDs are cyclic oligosaccharides derived from starch containing six (α CD), seven (β CD), eight
97 (γ CD) or more (α -1,4)-linked α -D-glucopyranose units (Tong, 2001). Due to this specific
98 structure of hydrophobic inner cavity and hydrophilic outer surface, CDs have the almost unique
99 ability to form inclusion complexes with various organic, inorganic, biological and
100 pharmaceutical molecules through non-covalent interactions (Dahan, Miller, Hoffman, Amidon
101 & Amidon, 2010). Since natural CDs, in particular β CD, show limited aqueous solubility, new
102 modified CDs with substitution of the hydrogen bond-forming hydroxyl groups have been
103 developed. Examples of such modified CDs include the hydroxypropyl derivatives of β CD and
104 γ CD (i.e. HP β CD and HP γ CD), the randomly methylated β CD (RM β CD) and others (Brewster
105 & Loftsson, 2007). Up to now, all the properties of cyclodextrins or derivatives made them
106 suitable for applications in analytical chemistry, agriculture, the pharmaceutical field, in food
107 and toilet articles. In foods, CDs are used as molecular encapsulants to protect flavouring agents
108 or other additives during the rigorous processing methods, extending the shelf life of the food
109 item and preserving the product organoleptic properties. CDs are also used in the preparation of
110 controlled release powdered flavours and confectionery items and are being used for the
111 development of controlled-release active packaging systems (Del Valle, 2004; Koontz, Moffitt,
112 Marcy, O'Keefe, Duncan & Long, 2010).

113 Aiming at the development of an active food packaging for fresh products, the goal of this study
114 was to increase RV, PT and PS aqueous solubility using hydropropyl-beta-cyclodextrin (HP- β -
115 CD), hydropropyl-gamma-cyclodextrin (HP- γ -CD) and bile salts (sodium cholate and sodium
116 deoxycholate). The system that enabled the highest fold-increase in the aqueous solubility of test
117 compounds was further characterized by Fourier transform infrared spectroscopy (FTIR),
118 differential scanning calorimetry (DSC), powder X-ray diffraction (DRX) and $^1\text{H-NMR}$
119 spectroscopy and its ability to improve test compounds photostability was also investigated.

120

121 **Materials and Methods**

122

123 **Materials**

124 Pinosylvin and pterostilbene were purchased from Sequoia Research Products Limited
125 (Pangbourne, U.K.). *trans*-Resveratrol, sodium cholate and sodium deoxycholate were purchased
126 from TCI Europe N.V. (Zwijndrecht, Belgium). Since stilbenes are sensitive to light, reagents
127 and samples were stored in the dark. Regarding the CDs tested, hydroxypropyl- β -CD (HP- β -CD;
128 KLEPTOSE[®] HP, $M_w=1399$ g/mol) was kindly provided by Roquette Freres S.A. (Lestrem,
129 France) and hydroxypropyl- γ -CD (HP- γ -CD; $M_w=1580$ g/mol) was purchased from Sigma-
130 Aldrich.

131

132 **HPLC analysis of stilbenes**

133 Stilbene quantification was carried out using an Agilent 1290 Infinity LC HPLC system
134 (Waldbronn, Germany) equipped with an Agilent 1290 Infinity Diode Array Detector (G4212A
135 DAD). Compound separation was performed using a Zorbax 300 SB-C₁₈ reversed-phase

136 analytical column (5 μm , 4.6 mm \times 150 mm) acquired from Soquímica (Lisbon, Portugal). The
137 composition of mobile phase was a mixture of 0.1% (v/v) formic acid solution in purified water
138 (18.2 M Ω cm at 25°C) and acetonitrile (52:48, v/v). The mobile phase was filtered under
139 vacuum (0.2 μm hydrophilic polypropylene filter) and degassed for 30 min in an ultrasonic bath
140 before use. An isocratic flow of 1.0 mL/min was applied and the column oven was maintained at
141 25 °C. The wavelength defined for monitoring stilbenes was 306 nm for *trans*-stilbenes isomers.
142 The retention times obtained for *trans*-resveratrol, *trans*-pinosylvin and *trans*-pterostilbene were
143 1.8, 2.7 and 4.7 minutes, respectively. This method was validated according to the guidelines
144 provided by the Food and Drug Administration (FDA) (Food and Drug Administration, 2001)
145 and International Conference on Harmonization (ICH) (Harmonization, 2005) and the
146 parameters studied were linearity, intermediate, intra- and interday precision and accuracy.

147

148 **Critical micellar concentration (CMC) determination**

149 In order to determine sodium cholate and sodium deoxycholate CMC, two methods were used.
150 The first method consisted of a non-invasive method based on conductivity measurements (Posa,
151 Guzsany & Csanadi, 2009) and the second one was an invasive method based on Coomassie
152 Brilliant Blue R-250 spectral shift (Courtney, Simpson & Beachey, 1986).

153

154 **Phase solubility studies of stilbene-CD complexes**

155 CD solutions were prepared at different concentrations (0, 0.025, 0.05, 0.10, 0.20 and 0.30 M^{-1})
156 in PBS buffer (pH 7.0). A volume of 500 μL of each CD solution was added to an excess amount
157 of stilbenes (20 mg). The resulting suspensions were vortexed and sonicated for 1h in an
158 ultrasonic bath with ice. The suspensions were kept protected from light on an orbital shaker at
159 25 °C, 250 rpm for 24h. This equilibrium time was previous determined by preliminary studies.

160 The resulting suspensions were filtered through 0.2 μm PVDF syringe filters (Millipore, MA,
161 USA) to obtain clear solutions that were properly diluted with methanol:PBS (pH 7.4) (1:1) to
162 the calibration range (1-100 $\mu\text{g}/\text{mL}$) and measured by HPLC after method validation.

163 The apparent stability constants ($K_{1:1}$ and $K_{1:2}$) were calculated according to the equations
164 established by Higuchi and Connors (Higuchi & Connors, 1965).

165

166 **Resveratrol solubility studies with bile salts**

167 Solutions of bile salts were prepared in PBS buffer (pH 7.4) at the following concentrations: 0,
168 0.25, 0.5, 1.0, 1.5, and 2.0 CMC value (mM) for each bile salt respectively. An excess of
169 stilbenes (0.5, 1 and 5 mg of resveratrol, pterostilbene and pinosylvin, respectively) was added to
170 500 μL of bile salts solutions and the suspensions were incubated protected from light in an
171 orbital shake at 25 $^{\circ}\text{C}$, 250 rpm for 24h, since resveratrol solubility did not increase with
172 increasing time periods. Solutions were sealed with parafilm and protected from light. Control
173 solution was 1 mg/mL of stilbene in PBS buffer prepared in the same way. Before UPLC
174 analysis, the samples were filtered through 0.45 μm PVDF syringe filters (Millipore, MA, USA),
175 diluted with methanol:PBS (pH 7.4) (1:1) to the calibration range (1-100 $\mu\text{g}/\text{mL}$) and injected
176 into the UPLC system.

177

178 **Characterization of stilbene-CD complexes**

179 Preparation of physical mixtures

180 Physical mixtures of stilbene and CD were prepared by simply blending uniformly in a mortar
181 resveratrol, pterostilbene and pinosylvin with HP- β -CD or HP- γ -CD, previously sieved (200 μm
182 mesh), with 1:1 or 1:2 molar ratios, depending on the stoichiometry obtained in the phase-
183 solubility studies.

184

185 Preparation of inclusion complexes for solid characterization

186 Inclusion complex samples were prepared as described previously in a 1:1 or 1:2 molar rates,
187 according to the apparent stability constants obtained, frozen at -80 °C for at least 24 h,
188 lyophilized and stored in a dessicator until used.

189 Fourier Transform Infrared–Attenuated Transmitted Reflectance Spectroscopy (FTIR-ATR)
190 studies

191 Spectra were recorded using a Thermo Scientific Nicolet iS10 FT-IR spectrometer associated
192 with a Smart iTR* ATR horizontal reflexion accessory. FT-IR spectra acquisitions of stilbenes,
193 cyclodextrins, inclusion complexes and physical mixtures were directly performed in powder
194 samples with the application of 256 scans at a resolution of 4 cm⁻¹ in the a spectral region
195 between 4000 and 450 cm⁻¹.

196 Thermal analysis

197 Differential scanning calorimetry (DSC) measurements of the pure compounds, physical

198 mixtures and inclusion complexes were carried out using a Shimadzu DSC-50 System
199 (Shimadzu, Kyoto, Japan) with a DSC equipped with a computerized data station TA-50WS/PC.

200 The thermal behaviour was studied by heating the samples (~2 mg) in a sealed aluminium pan
201 from 50–300 °C, at a rate of 10 °C/min and under a nitrogen flow of 10 mL/min, using an empty
202 pan sealed as reference. Indium (99.98%, mp 156.65 °C, Aldrich, Milwaukee, USA) was used as
203 standard for calibrating the temperature.

204 X-ray diffraction (XRD)

205 X-ray powder diffraction patterns were obtained at room temperature with a Rigaku, model

206 DMAX III/C diffractometer system equipped with copper (Cu) as anode material and a graphite

207 monochromator using a voltage of 30 kV and a current of 35 mA. The diffractograms were

208 recorded in the 2θ angle range between $3\text{--}60^\circ$ and the process parameters were set at: scan step

209 size of $2\theta/\text{min}$ with a total acquisition time of 1 h. Crystallinity was determined by comparing

210 some representative peak heights in the diffraction patterns of the inclusion complexes and

211 physical mixtures with a reference. The relation used for the calculation of the crystallinity was
212 the relative degree of crystallinity (RDC) = I_{Sa}/I_{Ref} , where I_{Sa} is the peak height of the sample
213 (inclusion complexes and physical mixtures) under investigation and I_{Ref} is the peak height of the
214 same angle for the reference (Figueiras, Carvalho, Ribeiro, Torres-Labandeira & Veiga, 2007).
215 For this analysis, the peak with the higher intensity was selected. Resveratrol, pterostilbene and
216 pinosylvin were used as reference samples for calculating RDC values.

217 ^1H Nuclear Magnetic Resonance (NMR) studies

218 ^1H NMR spectroscopy was performed at a temperature of 298 K on a Bruker Avance III 600
219 MHz spectrometer operating at 14.09 Tesla observing ^1H at 600.13 MHz. The spectrometer was
220 equipped with a three-channel (^1H , ^{13}C and ^{15}N) cryoprobe and all spectra were processed with
221 the software Topspin 2.0 (Bruker). Trimethylphosphite (TMP) was used as internal standard at a
222 concentration of 2% (v/v). Stilbene and cyclodextrin solutions were prepared at 2 mM in
223 $\text{D}_2\text{O}/\text{DMSO-d}_6$ (1:10, v/v). Inclusion complexes solutions were prepared at 2 mM of each
224 compound in $\text{D}_2\text{O}/\text{DMSO-d}_6$ (1:10, v/v).

225

226 **Photostability studies**

227 Stilbene inclusion complexes were prepared in the same way as for the FTIR studies, frozen at -
228 80 °C, lyophilized, reconstituted in water and diluted with methanol to a final concentration of 1
229 mg/mL. Stilbene solutions were also prepared at 1 mg/mL in methanol.

230 Photostability studies of pure and complexed stilbenes were performed under a standard
231 fluorescent supermarket light (OSRAM L36 W/76). The samples were placed in tightly sealed
232 glass vials kept at distance of 27 cm from the lamp for 76 days at 4 °C and room temperature
233 (20-22 °C). Control samples for each temperature were kept in the dark for the same time period.
234 In order to assess compound photostability, samples were taken at regular time intervals and the

235 stilbenes were quantified by UPLC. Photodegradation was expressed by the reduction in the
236 *trans* isomer of each stilbene throughout the assay by comparison with the initial values.

237

238 **Results and Discussion**

239 Resveratrol and its analogues pterostilbene and pinosylvin are known to possess a low aqueous
240 solubility which has limited their use in numerous fields. Since cyclodextrins and micellar
241 systems such as bile acids are known to increase the solubility of a vast range of compounds and
242 are also able to protect them from external agents, in this work these two systems were chosen to
243 incorporate resveratrol, pterostilbene and pinosylvin in order to evaluate their ability to increase
244 compound solubility and stability.

245

246 **Method validation**

247 Usually, the methods preferred to quantify stilbenes in aqueous solutions are based on UV or
248 fluorescence detection and can be performed with or without chromatographic separation.
249 However, as stilbenes can occur as *trans*- or *cis*-isomers, a method capable of detecting and
250 resolving these two isomers is more suitable for quantification. Considering that, in this work,
251 we aimed at quantifying only the *trans*-isomers of stilbenes and, for this purpose, a methodology
252 using high performance liquid chromatography (HPLC) coupled to UV detection method was
253 developed and validated in terms of linearity, intermediate, intra- and interday precision and
254 accuracy, following a 5-day validation protocol. The chromatographic conditions described
255 allowed the successful elution of RV, PS and PT at 1.841, 2.743 and 4.748 min, respectively
256 (Figure 1a). To evaluate the method's linearity, several solutions of stilbenes with concentrations
257 ranging from 1 to 100 µg/mL were prepared (eight calibrators evenly distributed and five
258 replicates) and analyzed as described above. Together with each calibration curve, three quality

259 control samples (QC) at low (LQC: 1 $\mu\text{g/mL}$) and medium (MQC: 50 $\mu\text{g/mL}$) and high (HQC:
260 100 $\mu\text{g/mL}$) concentrations ($n=3$) were also analysed. Calibration curves were obtained by
261 plotting the peak–area of each analyte against analyte concentration. The acceptance criteria
262 included a determination coefficient of at least 0.99 and the calibrators' accuracy within a ± 15
263 %, with the exception of the lower limit of quantitation (LLOQ), 1 $\mu\text{g/mL}$, where ± 20 % was
264 accepted. Due to the wide calibration range, weighted least squares regressions were adopted.
265 Six weighting factors were evaluated for each analyte ($1/\sqrt{x}$, $1/x$, $1/x^2$, $1/\sqrt{y}$, $1/y$, $1/y^2$), and the
266 one originating the best results was selected. Using each of those factors, the mean relative errors
267 of each calibrator were calculated and their absolute value was summed. The weighting factor
268 $1/x^2$ was chosen for all analytes since the sum of errors obtained was smaller while presenting
269 simultaneously a mean R^2 value of at least 0.99 (Figure 1d). By means of these weighted least
270 squares regressions, linear relationships were obtained ($R^2 \geq 0.99$) (Figure 1b), and the relative
271 error [mean relative error (bias) between measured and spiked concentrations] was in accordance
272 with the above-mentioned criteria ($\pm 15\%$ for all concentrations, except at the lower limit of
273 quantitation where $\pm 20\%$ was acceptable). The lowest concentration used for quantification (1
274 $\mu\text{g/mL}$) for each analyte is considerably higher than the LLOQ already described by other
275 authors for resveratrol, pterostilbene and pinosylvin quantification, reaching limits within a 10–
276 20 ng/mL range (Lin et al., 2009; Paulo, Domingues, Queiroz & Gallardo, 2011; Roupe, Halls &
277 Davies, 2005). However, these limits are adequate for monitoring stilbene concentration in this
278 work, as their concentrations in inclusion complexes and micelles are usually very high
279 (Atanackovic et al., 2009; Das et al., 2008), even requiring serial dilutions to fall within the
280 dynamic range of the assay.

281 Interday precision and accuracy (Figure 1c) were evaluated at eight concentrations (1, 2.5, 5, 10,
282 25, 50, 70 and 100 $\mu\text{g/mL}$). The calculated CVs were lower than 3.5% for all compounds at all

283 concentration levels, while accuracy (in terms of mean relative error) was within a $\pm 9\%$ interval.
284 The CVs presented are lower than those described in literature for stilbene quantification by
285 HPLC-DAD (Careri, Corradini, Elviri, Nicoletti & Zagnoni, 2003; Paulo et al., 2011) and could
286 be related to the fact that an extraction procedure, usually a source of variability, is not
287 performed in this work (Juan, Maijo & Planas, 2010). Intra-day precision and accuracy (Figure
288 1d) were determined using 4 standard concentrations (1, 10, 50 and 100 $\mu\text{g}/\text{mL}$) prepared and
289 analyzed as mentioned above (six replicates for each concentration). The obtained coefficients of
290 variation (CVs) were lower than 3% for all the compounds at all tested concentrations,
291 presenting a mean relative error within a $\pm 9\%$ interval. Additionally, intermediate precision and
292 accuracy (Figure 1e) were assessed at 3 concentrations (15, 40 and 80 $\mu\text{g}/\text{mL}$) performed in
293 triplicate over the 5-day validation period ($n=15$). The results showed that the obtained CVs were
294 always lower than 3.7% and the relative error was within a $\pm 6\%$ interval from the target
295 concentration.

296 Overall, the HPLC-DAD method described allowed the quantification of RV, PT and PS *trans*-
297 isomers within a 6 min chromatographic run and was successful validated regarding all the
298 parameters evaluated, since CV and relative error values were always lower than 15% for all
299 criteria.

300

301 **Solubilization of resveratrol with bile salts and CDs**302 Bile salts

303 The physiological and therapeutic properties of some bile salts are, essentially, due to their
304 ability to form micelles, which facilitate the dissolution and release of molecules with poor
305 aqueous solubility (Reis, Moutinho, Matos, de Castro, Gameiro & Lima, 2004). Critical micellar
306 concentration (CMC) is a fundamental parameter in the evaluation of the biological activity of
307 bile salts. The CMC of a surfactant is defined as the solutes concentration at which micelles first
308 appear in solution and, in practical terms, is related to appreciable changes in surface tension,
309 solubilisation of other organic molecules, among other parameters (Reis et al., 2004). Many
310 different techniques can be used for determination of CMCs and are generally classified in
311 invasive (dye solubilization and spectral shift, etc.) and non-invasive methods (surface tension,
312 conductometry, etc.) (Roda, Hofmann & Mysels, 1983). In this context, two methods for
313 determining the CMC values of sodium cholate and sodium deoxycholate in buffered solutions
314 were evaluated. The chosen methods were conductometry (non-invasive) and Coomassie
315 Brilliant Blue R-250 dye solubilisation (invasive method). The CMC values obtained for sodium
316 cholate and sodium deoxycholate were, approximately, 10 and 3 mM, respectively
317 (Supplementary file S1) being similar to the ones described in the literature (Atanackovic et al.,
318 2009; Matsuoka & Moroi, 2002). As expected, each method yielded slightly different CMC
319 values, with the higher values being obtained for conductometry, which is in agreement with
320 previous results obtained by other authors (Poša, Guzsány & Csanádi, 2010). Since, generally,
321 the values obtained using conductometry are over-estimated, the CMC values determined by this
322 method were used to assess the improvement of stilbene solubility by bile salts. As a
323 consequence of the membrane-toxic properties of micelles due to the disruption of membrane

324 integrity, the highest concentration of bile salt used corresponded to 2xCMC (Atanackovic et al.,
325 2009). Sodium cholate was able to increase RV, PT and PS solubility up to 0.2, 1.2 and 8.0
326 mg/mL, respectively (Figure 2a,b,c); whereas, sodium deoxycholate increased compounds'
327 aqueous solubility to a smaller extent, yielding a maximum of 1 mg/mL of solubilised
328 compound, in the case of PS. In the solubility diagrams obtained for RV and PT, there is a clear
329 increase in solubility after reaching the CMC value, as expected.

330 Modified CDs

331 As an alternative agent for increasing stilbene solubility and stability, two modified CDs
332 (hydropropyl- β -CD and hydroxypropyl- γ -CD) were evaluated in this work. These modified CDs
333 were preferred over natural CDs, since their solubility in aqueous solutions is higher, thus
334 resulting in higher solubility of the inclusion complexes formed (Challa, Ahuja, Ali & Khar,
335 2005). Hydrophilic CDs, namely HP- β -CD are considered non-toxic at low to moderate oral and
336 intravenous doses and are more toxicologically benign than the natural β -CD (Irie & Uekama,
337 1997). Although the information regarding HP- γ -CD is limited, it is known that it possesses one
338 of lowest haemolytic effect on human erythrocytes when compared with other natural or
339 modified CDs (Brewster et al., 2007). The phase-solubility studies revealed that HP- γ -CD and
340 HP- β -CD form inclusion complexes with RV and PT in a 1:1 stoichiometry (Figure 2d), due to
341 the correlation coefficients obtained from phase-solubility diagrams, which exhibited a A_L type
342 curve (linear increases of drug solubility as a function of CD concentration) whilst inclusion
343 complexes of both CDs and PS showed a 1:2 stoichiometry and a A_N type curve (negatively
344 deviating isotherms) (data not shown), meaning that the formation of higher order complexes is
345 occurring (Brewster et al., 2007). This 1:2 stoichiometry is described for the first time for these
346 complexes, considering that the only data available for these complexes referred a 1:1
347 stoichiometry (Lopez-Nicolas et al., 2009a). The differences obtained might be related with the

348 design of the study and methodologies used, since different techniques (fluorescence
349 spectroscopy) and lower CD concentrations (≥ 0.1 M) were used in comparison to this work.
350 These A_N profiles have several explanations, including bulk changes imparted to the solvent by
351 the CD at various concentrations and also due to self-association of the CD at high
352 concentrations (Brewster et al., 2007). The apparent stability constants (K_S) obtained for RV are
353 lower than the ones previously described (Das et al., 2008; Lopez-Nicolas et al., 2009b), though
354 the maximum amount of resveratrol solubilised at the higher CD concentration (0.3 M) is within
355 the range of values reported (Das et al., 2008). In the case of PT, despite the K_S values for HP- β -
356 CD are within the same order of magnitude as the ones obtained by Lopez-Nicolas and co-
357 authors, they are slightly lower (Lopez-Nicolas et al., 2009b). For PS, the apparent stability
358 constants for both HP- γ -CD and HP- β -CD were significantly lower than the ones previously
359 obtained (Lopez-Nicolas et al., 2009a), which could be related with the phase-solubility profiles
360 obtained.

361 Bile salts versus CDs

362 When comparing stilbene solubility improvement, modified CDs allowed a greater increment in
363 compound solubility (4-6 log-fold increase) when compared to bile salts (≤ 4.5 log-fold increase)
364 (Figure 2e). In fact, CDs provided the obtention of inclusion complexes with solubilities more
365 than 700,000-fold higher than the aqueous solubility of test compound (S_0) while bile salts
366 enhanced stilbene solubility up to 25,000 times. The values obtained for resveratrol aqueous
367 solubility with HP- β -CD (38.74 mg/mL) (Figure 2d) was slightly higher than the one described
368 by Das and co-authors (30 mg/mL), probably due to the higher orbital rotation (250 rpm) used in
369 our work. The highest increase in solubility was verified for PT, the stilbene with the lowest
370 aqueous solubility ($S_0=1.96 \times 10^{-5}$ M). When comparing the solubility enhancement between RV
371 ($S_0=1.43 \times 10^{-4}$ M) and PS ($S_0=1.91 \times 10^{-3}$ M), modified CDs were able to solubilise RV to a

372 greater extent than PS and bile salts enable the solubilisation of PS in higher amount, instead of
373 RV. Overall, CDs produced the highest improvements in stilbene aqueous solubility, which may
374 be a result of the low bile salt concentrations used, considering that, for instance, Gokturk and
375 co-authors obtained similar solubility for test compounds when using CDs and micelles, but the
376 surfactant concentration was much higher than the CMC (approximately 6xCMC) (Gokturk,
377 Caliskan, Talman & Var, 2012). Overall, these results clearly state the enormous impact of
378 cyclodextrins and bile salts in improving the aqueous solubility of several compounds, with 10^3
379 to 10^6 -fold increase in the amount of solubilised compounds. Though the complexation of
380 stilbenes in modified CDs have already been described, the characterization of the inclusion
381 complexes formed has not yet been reported. Hence, the inclusion complexes between HP- γ -CD
382 and HP- β -CD and RV, PT and PS were further characterized by FTIR, XRD, DSC and ^1H NMR.

383

384 **Inclusion complex characterization**

385 Figures 3a–3f show the multiple FTIR spectra obtained for each one of the six inclusion
386 complexes formed. Each graph is composed by the FTIR spectra of inclusion complexes,
387 physical mixtures and respective stilbene and cyclodextrin. RV and PS spectra, in the range of
388 $1700\text{--}700\text{ cm}^{-1}$, exhibited four characteristic intense bands at 1600-1605, 1583-1585, 1381-1385,
389 $960\text{--}964\text{ cm}^{-1}$ corresponding to C-C aromatic double bond stretching, C-C olefinic stretching, C-
390 O stretching and *trans* C-H olefinic stretching (Bertacche et al., 2006). For PT, only three intense
391 and visible bands in the selected range (1602 , 1584 and 961 cm^{-1}) were identified but a fourth
392 intense band corresponding to the aromatic methoxy groups was visible at 2832 cm^{-1} (Panickera
393 et al., 2010) (data not shown). Regarding the inclusion complexes obtained for all stilbenes (RV,
394 PT and PS) (Figure 3a,d), the spectra showed changes in the spectral features of guest molecule,
395 since only the peak corresponding to C-C aromatic double bond stretching was identified with a

396 band wavenumber slightly deviated from the ones obtained for guest molecules, which
397 undoubtedly confirmed the presence of RV, PT and PS within the complex in the lyophilized
398 systems. Taken together with the fact that physical mixtures exhibited the majority of guest
399 molecule peaks with almost equal band wavenumbers, these evidences indicate the formation of
400 weak interactions between CDs and stilbenes in these systems (Figueiras et al., 2007).

401 Power X-ray diffractometry was used to further confirm the formation of inclusion complex
402 between stilbenes and HP-CDs. The X-ray diffraction (XRD) patterns for each compound, CD,
403 physical mixtures and inclusion complexes are displayed in Figure 4. In addition to the XRD
404 patterns, crystallinity was also determined by comparing some representative peak heights in the
405 diffraction patterns of the inclusion complexes and physical mixtures with those of a reference
406 (Supplementary file S2). In the X-ray diffractograms of RV, PT and PS was possible to observe
407 several sharp peaks suggesting that these compounds are present in a crystalline form.
408 Nonetheless, the XRD patterns for HP-CDs confirm its amorphous form, since no sharp peaks
409 could be discriminated (Williams, Mahaguna & Sriwongjanya, 1998). In the case of physical
410 mixtures, the XRD diffractograms are a superposition of stilbene and CD single component.
411 However, there was a decrease in peak intensity meaning a possible loss in crystallinity that can
412 be due to the amorphous character of the CD (Ribeiro, Figueiras, Santos & Veiga, 2008) used
413 and also due to the mixing time of the physical mixture, possibly causing a starting complexation
414 (Bertacche et al., 2006). Inclusion complexes revealed a stilbene amorphization with no
415 detectable peak in the XRD patterns. Furthermore, these results are corroborated by the RDC
416 values obtained for both physical mixtures and inclusion complexes, revealing a more
417 pronounced decrease in the relative crystallinity of the inclusion complexes when compared to
418 physical mixtures.

419 Thermal analysis has routinely been used as a method to characterize cyclodextrins complexes.
420 Supplementary file S3 shows the DSC thermograms of stilbenes, cyclodextrins, physical
421 mixtures and inclusion complexes. The thermograms obtained for each stilbene were typical of
422 crystalline anhydrous compounds with a sharp melting endothermic peak obtained at 268.45 °C
423 for RV, 94.87 °C for PT and 157.18 °C for PS which is in accordance with the melting points
424 provided by the manufacturers. HP- β -CD and HP- γ -CD yielded a very broad endothermic effect,
425 reaching a maximum value around 70-80 °C, due to the release of water molecules from the CD
426 cavity (Fernandes, Teresa Vieira & Veiga, 2002). In the DSC thermograms of all complexes, the
427 absence of the melting endothermic peak of each stilbene can be noticed. This provided some
428 evidence of inclusion complexation, since when guest molecules are embedded in the CD cavity,
429 their melting points usually shift to a different temperature or disappear within the temperature
430 range of CD decomposition (Karoyo, Sidhu, Wilson & Hazendonk, 2013). The endothermic
431 peak of each stilbene was not visible in the DSC curves of the physical mixtures, as opposed to
432 what should be expected. This fact could be due to the overlap of the CD dehydration peak with
433 PT melting peak, to an excess amount of CD in PS mixtures due to the 1:2 stoichiometry or even
434 to the fact that some complexation could have started during the mixing of the physical mixtures
435 (Bertacche et al., 2006). Taken together, FTIR, XRD and DSC results undoubtedly confirmed
436 the formation of inclusion complexes between stilbenes and CDs. However, a more thorough
437 molecular characterization of the interactions involved in each complex formation was needed.
438 Over the past decades, NMR techniques have been used to study cyclodextrins inclusion
439 complexes. The ^1H NMR spectra for each inclusion complex and stilbene are shown in
440 Supplementary file S4, with the full spectra (stilbene and CD) (Supplementary file S4a, c and e)
441 and only compound spectra (Supplementary file S4b, d and f) being represented for a better
442 visualization of ^1H NMR chemical shift displacements. As can be seen in full spectra, it was not

443 possible to assign the peaks corresponding to HP- β -CD and HP- γ -CD due to the very broad
444 peaks obtained, a result of the fact that these modified CDs consists of a mixture of a number of
445 related derivatives with different degrees of substitution $[(C_3H_6O)_nH]$ and isomeric forms
446 (Fernandes, Carvalho, Pereira da Costa & Veiga, 2003). Therefore, it was only possible to
447 observe the shifts of stilbene protons in the presence of HP-CDs, which provided information
448 about the existence of an interaction in solution. The 1H -chemical shifts of RV, PT and PS are
449 reported in Table 1. As shown, an upfield shift was observed for almost all the protons of RV,
450 PT and PS in the presence of both HP- β -CD and HP- γ -CD. The upfields of RV, PT and PS
451 protons were larger for HP- γ -CD in comparison to HP- β -CD, implying a stronger interaction
452 with HP- γ -CD, despite the similarity in the K_S values obtained for each CD. The hydroxypropyl
453 substitution of CDs could result in steric hindrance around the guest molecules, making the
454 entrance of the guest molecule inside CD hydrophobic cavity more difficult. Since HP- γ -CD has
455 a larger cavity than HP- β -CD, this could result in the alleviation of the steric hindrance effect,
456 thus promoting the entrance of the guest molecule inside the CD cavity (Fernandes et al., 2002).
457 The largest upfield shifts were obtained for H₂, H₃, H₄ and H₅ stilbene protons, indicating that the
458 double bond protons and closer aromatic protons are mainly involved in the formation of the
459 complex (Bertacche et al., 2006; Boudad, Legrand, Lebas, Cheron, Duchene & Ponchel, 2001)
460 as they experience significant perturbation upon complexation. Since this is the most
461 hydrophobic moiety of the guest molecules, it would be expected to be included within the
462 cyclodextrins cavity, leaving the hydroxyl groups in the extremities in contact with the
463 hydrophilic medium. However, this perturbation in the double bond caused by a possible
464 interaction with the CD did not result in any *cis-trans* isomerisation of stilbene, since no *trans*-
465 isomer reduction was visible by HPLC-DAD upon complexation.

466

467 **Photostability studies**

468 One of the main issues one working with stilbenes is their *cis-trans* isomerisation upon exposure
469 to UV light (Paulo et al., 2011). Although only a few data are available, it is widely accepted that
470 the *trans*-isomers have higher bioactivity than the *cis*-isomers (Waffo-Teguo et al., 2001).
471 Therefore, the ability of the CDs in improving *trans*-stilbene stability was verified. Since the
472 final application of these complexes is in the development of an active packaging for meat
473 products, photostability studies were conducted by exposure to a standard supermarket
474 fluorescent light to simulated meat packaging storage conditions. The photostability of RV, PT
475 and PS and corresponding inclusion complexes was investigated under different storage
476 temperatures (4 and 20 °C), in the dark and under light exposure. Since the HPLC-DAD method
477 was validated only for *trans*-isomers, it was only possible to quantify *trans*-stilbenes and, so, the
478 results are expressed as the percentage of *trans*-isomer reduction over time. In general, both
479 stilbenes and inclusion complexes are more stable at 4 °C than at 20 °C (Figure 5). Overall, the
480 complexation of RV, PT and PS with HP- β -CD and HP- γ -CD, allowed an increase in stilbene
481 photostability at 4 °C, that was more significant in the case of HP- β -CD at least until 14 days of
482 exposure. PS and PS complexes exhibited the highest photostability, since after 21 days of
483 exposure, only a 30% reduction of *trans*-PS was observed. This increase in stilbene
484 photostability could be related with the interaction of the CD with the protons involved in the
485 *cis-trans* isomerisation, thus blocking, to some extent, the conversion of *trans*- to *cis*-stilbenes.

486

487 **Conclusions**

488 Nowadays, the use of antimicrobial and antioxidants as ingredients in active packaging is one of
489 the main goals of the food industry. Due to the consumers' demand for natural alternatives and to
490 stilbenes proved biological activities, they can be considered ideal candidates to be incorporated

491 in these packaging systems. However, some problems related to these compounds' stability and
492 solubility need to be overcome to improve their efficacy in the package material. Toward this
493 aim, it was evaluated the increase in stilbene solubility by CDs and bile salts and concluded that
494 CDs proved to be more beneficial for increasing stilbene solubility with the advantage of being
495 less toxic to humans. Afterwards, a thorough characterization of the inclusion complexes formed
496 between RV, PT or PS and HP- β -CD or HP- γ -CD was performed, which confirmed that
497 formation of stable inclusion complexes and even shed some light about the molecular
498 interactions between guest molecules and cyclodextrins. Besides improving stilbene solubility,
499 CDs also increased their photostability, which can circumvent stilbene reactivity and encourage
500 their application not only in the food industry but also in the pharmaceutical industry.

651

652 **Figure 1:** HPLC-DAD stilbene quantification linearity and validation data: a) typical HPLC-
653 DAD chromatogram ($\lambda=306$ nm), b) linearity data (n=5), c) inter-day precision and accuracy
654 (n=5), d) intra-day precision and accuracy (n=6) and e) intermediate precision and accuracy
655 (n=15). All concentrations are in $\mu\text{g/mL}$; CV, coefficient of variation; RE, relative error
656 $[(\text{measured concentration}-\text{spiked concentration}/\text{spiked concentration})\times 100]$. When applicable,
657 values are presented as mean values \pm standard deviation.

658

659 **Figure 2:** Comparison of stilbene solubilization by bile salts and cyclodextrins. Solubilization of
660 a) resveratrol, b) Pterostilbene, c) pinosylvin by buffered solutions of sodium cholate and
661 deoxycholate at 37 °C, d) K_s values, stoichiometry and correlation coefficients for stilbene-HP-CD
662 complexes at 25 °C and pH=7.0 and e) solubility enhancement using bile salts or
663 hydroxypropylated-CDs.

664

677 **Highlights**

678

679 Novel HPLC-DAD method for the simultaneous determination of 3 *trans*-stilbenes

680 Comparison of stilbene solubility in inclusion complexes and micellar systems

681 Cyclodextrins increased stilbene solubility up to 6 log-fold increase

682 Cyclodextrin-stilbene interaction occurs mainly through the double bond protons

683 Stilbene photostability was increased due to the inclusion in CDs
