30 Running title: Vertebral Compression Fractures In Paleopathology
31
32
33
34

35 ABSTRACT

36
37
38 Vertebral compression fractures are the most common osteoporotic fractures
39 in postmenopausal women. Notwithstanding, its clinical diagnosis remains
40 ambiguous. In paleopathological studies vertebral fractures and/or
41 deformations are frequently disregarded. When observed, vertebral
42 compression fractures are usually recorded without the support of quantifiable
43 and comparable protocols. As such, a semi-quantitative method for vertebral
44 compression fracture assessment (Genant et al., 1993) was applied to a large
45 sample (N=198) from the Coimbra Identified Skeletal Collection, Portugal, and
46 the reliability of the method was tested. Vertebral fracture scoring agreement
47 was evaluated with the Kappa statistic and the percent of agreement. Intra-
48 observer and inter-observer agreement are both appropriate. The Genant's
49 semi-quantitative scoring methodology is easy to apply and highly

11 12 13 14 INTRODUCTION 15

16
17 Osteoporosis (OP) is a metabolic pathological disorder characterized by the
18 decrease in bone mass and quality and subsequent increase in fracture risk
19 (NIH Consensus Development Panel, 2001). OP is essentially symptomless
20 prior to bone fracture (Wylie, 2010), being classically associated with fractures
21 in the proximal femur, the distal radius and the vertebral body (Johnell and
22 Kanis, 2006).
23
24
25
26

27
28 Vertebral compression fractures and/or deformations are both the most
29 common and underdiagnosed of the so-called osteoporotic fractures in
30 postmenopausal women (Johnell and Kanis, 2006; Grados et al., 2009). The
31 clinical diagnosis of vertebral compression fractures is ambiguous, inasmuch
32 as there is not a consensual definition. They are frequently asymptomatic
33 which translates in their underestimation in clinical practice (Delmas et al.,
34 2005; Grados et al., 2009). Visual assessment is the most common method
35 used in the clinical practice, but the results are exceedingly reliant on the
36 knowledge of the observer (Ferrar et al., 2005; Olmez et al., 2005).
37
38
39
40
41
42
43

44
45 Descriptions of vertebral compression fractures in the paleopathological
46 literature are not infrequent. Nevertheless, they commonly denote anecdotal
47 cases (e.g., Foldes et al., 1995; Ortner, 2003; Reis et al., 2003; Sambrook et
48 al., 1988; Strouhal et al., 2003), or refer to visual qualitative methods for the
49 identification of vertebral fractures (e.g., Domett and Tayles, 2006; Hirata and
50 Morimoto, 1994; Ives, 2007; Mays, 1996; Mays, 2006; Mays et al., 2006;
51 Mensforth and Latimer, 1989; Snow, 1948). The «Spine Score» (Barnett and
52 Nordin, 1960) has been employed for the definition of vertebral fractures in
53
54
55
56
57
58
59
60

1
2
3 archaeological populations (Gonzalez-Reimers et al., 2004). Other studies
4 (e.g., Curate et al., 2009; Curate et al., 2013; Garcia, 2007) used Genant's
5 semi-quantitative method (Genant et al., 1993) for the evaluation of vertebral
6 compression fractures.
7
8

9
10
11 Reproducible methods for the assessment of vertebral compression fractures,
12 defined by unequivocal criteria, are to be favored in clinical and
13 epidemiological settings, as well as in archaeological contexts. As such, this
14 study aims to test the reliability of a semi-quantitative method for vertebral
15 compression fractures and/or deformations assessment (presence/absence of
16 fracture) in a skeletal sample from the Coimbra Identified Skeletal Collection.
17
18
19

20 21 22 MATERIALS AND METHODS

23
24 The sample studied comprised 196 individuals from the Coimbra Identified
25 Skeletal Collection (Rocha, 1995), evenly distributed from both sexes, with an
26 age-at-death ranging from 20 to 96 years old. The sample included individuals
27 born between 1827 and 1914; and dead between 1910 and 1936. Individuals
28 were typically blue-collar workers with low socioeconomic status. Only
29 individuals with a complete vertebral column, without gross post-depositional
30 and pathological modifications at the vertebral column were included in the
31 sample.
32
33
34
35
36
37

38
39 Vertebral compression fractures and/or deformations were assessed
40 macroscopically in the T4 through L4 vertebrae, with the Genant's scoring
41 method (Genant et al., 1993). This semi-quantitative evaluation method is
42 based on the vertebral shape (wedge, concave or crush) and on decreases in
43 the anterior, posterior and/or middle vertebral heights (Figure 1), as follows:
44
45
46
47

- 48 1. Grade 0, no reduction;
- 49 2. Grade 1, minimal fracture, 20 – 25% decrease in any vertebral
50 height;
- 51 3. Grade 2, moderate fracture, 25 – 40% decrease;
- 52 4. Grade 3, severe fracture, +40% decrease.
53
54
55
56
57
58
59
60

1
2
3 The first author (FC, Obs1), an experienced observer, evaluated 196
4 individuals in two different occasions. The second author (TFS, Obs2), an
5 inexperienced observer, assessed 75 individuals after being clarified how to
6 use the method and without the aid of an anatomical atlas. Both intra- and
7 inter-observer variability in the assessment of vertebral fractures and/or
8 deformations (presence/absence) were evaluated with the percent of
9 agreement (%A; Watkins and Pacheco, 2000) and Cohen's Kappa (κ_c ; Cohen,
10 1960). The percent of agreement is defined as:

$$\%A = (N - N' / N) \times 100,$$

11
12 in which N corresponds to the total number of pairwise comparisons, and N' to
13 the number of discordant pairs. Cohen's Kappa coefficient measures pairwise
14 agreement for categorical variables, while correcting for projected chance
15 agreement (Carletta, 1996; Rothwell, 2000). In the case of intra-observer
16 reliability, agreement was assessed *per* subject, and not *per* vertebra. For
17 inter-observer variability, agreement was estimated *per* subject and *per*
18 vertebra. Bias index for the Kappa coefficient was also estimated (Sim and
19 Wright, 2005).

20
21 All measurements (anterior, posterior and middle vertebral heights) were
22 directly performed in the vertebrae, placed in lateral projection, with the aid of
23 a digital outside caliper. Statistical analyses were achieved with IBM® SPSS®
24 (version 19.0.0).

25 26 27 RESULTS

28
29 Both %A and κ_c suggest a remarkable level of intra-observer agreement
30 between observations *per* individual. Inter-observer variability was somewhat
31 higher but the measures of agreement between observers were also very
32 satisfactory, both *per* individual and *per* vertebra. Bias index for the Kappa
33 coefficient is very low (Table 1). Notwithstanding, while the inexperienced
34 observer correctly identified all the actual vertebral fractures/deformations, it
35 also incorrectly recorded grade 1 fractures/deformations in four individuals
36 that were not affected. Also, when both observers recorded a fracture, the

5
6

7 DISCUSSION

8
9
10 In paleopathological studies regarding trauma, vertebral fractures and/or
11 deformations are often ignored. When observed, vertebral compression
12 fractures are usually described without the assistance of quantifiable and
13 reproducible protocols (Curate et al., 2011).
14
15
16

17
18 Genant's scoring method (Genant et al., 1993) displays a binary classification
19 of vertebral fractures/deformations (present/absent), an evaluation of fracture
20 severity (grades 0 to 3) and a visualization of vertebral shape after fracture
21 (wedge, crush or concave). In this study, intra- and inter-observer reliability in
22 the assessment of vertebral fracture presence was evaluated. Intra-observer
23 agreement amongst observations was excellent, with a very high percent of
24 agreement, and a Kappa coefficient (non chance agreement) reflecting an
25 almost perfect agreement (Landis and Koch, 1977). Inter-observer agreement
26 was also very high, with the κ_c statistic suggesting a lower, but still substantial
27 agreement between observers. The literature on the subject supports these
28 results (Genant et al., 1993; Grados et al., 2009; Li et al., 1995).
29
30
31
32
33
34
35
36

37
38 Bias for the Kappa coefficient is low, and disagreement between observations
39 and observers is probably due to random error. Nonetheless, a negligible
40 tendency for the inexperienced observer to record non-existent fractures was
41 observed. The analysis of small isolated deformations in the vertebral column
42 is occasionally complex (El Maghraoui et al., 2009). Also, while 20%
43 reductions in any vertebral height have been proposed to define a minimal
44 fracture/deformity, it is clear that borderline cases are difficult to interpret
45 (Black et al., 1999) – especially in the case of untrained observers (Figure 2).
46 Although the Genant et al. (1993) method is straightforward, it shows a
47 learning curve, being dependent on training and experience (Grados et al.,
48 2009).

1
2
3 Visual assessment of vertebral compression fractures is simple and useful for
4 ruling out vertebral deformities due conditions other than osteoporosis.
5 Nevertheless, reproducibility is very low (Grados et al., 2009; Jensen et al.,
6 1984). Clinical and epidemiological trials with qualitative readings of vertebral
7 compression fractures demonstrate the great variability in the identification of
8 those fractures, which mainly corresponds to the interpretation of vertebral
9 radiographs without standardized guidance, references to anatomical atlas
10 and consensus readings by doctors and technicians (Black, 1999; Olmez et
11 al., 2005). Quantitative morphometric methods (e.g., Eastell et al. 1991;
12 McCloskey et al., 1993) are objective and reliable, being limited by a vast
13 group of errors: false positives, positioning problems, measurement
14 imprecisions (Grados et al., 2009; Weber et al., 1999). They also consider
15 vertebral body heights in relation to contiguous vertebrae – making these
16 methods unsuitable to evaluate compression fractures in isolated vertebrae.
17
18
19
20
21
22
23
24
25
26

27 The semi-quantitative method by Genant et al. (1993) is easy to apply,
28 effective in ruling out vertebral compression fractures due to causes other
29 than low bone mass, and highly reproducible. It is recommended by the
30 «International Society for Clinical Densitometry» to diagnose vertebral
31 fractures in the clinical setting (Schousboe et al., 2008). This study indicates
32 that it is also an appropriate standard scoring method for vertebral
33 compression fractures/deformities in paleopathological investigations: it is a
34 practical, accessible and relatively fast technique, it may be implemented
35 upon a complete vertebral column or an isolated vertebrae and mitigates
36 many of the differences between observations and observers.
